

What is claimed is:

1. An integrated circuit comprising:
a plurality of functional modules interconnected via a packet router,
each functional module having packet handling circuitry for generating and
receiving packets conveyed by the packet router;
5 wherein at least a first set of said functional modules, acting as initiator
modules, have packet handling circuitry which includes request packet
generation circuitry for generating request packets for implementing
transactions, each request packet including a destination indicator identifying a
destination of the packet and an operation field denoting the function to be
10 implemented by the request packet, wherein the operation field comprises
eight bits of which a packet type bit denotes the type of the packet, four
operation family bits denote the function to be implemented by the packet and
three operation qualifier bits act to qualify the function.
2. An integrated circuit according to claim 1, wherein a second set of
15 the functional modules, acting as target modules, each have packet handling
circuitry which includes packet receiver logic for receiving said request
packets and for generating respective response packets, wherein the packet
type bit distinguishes between request packets and response packets.
3. An integrated circuit according to claim 1 or 2, wherein the function
20 in each request packet is a memory access operation.
4. An integrated circuit according to claim 3, wherein one of said
operation family bits distinguishes between primitive memory access
operations involving a single request packet and compound memory access
operations involving a plurality of request packets.
- 25 5. An integrated circuit according to claim 1, wherein each request
packet includes a data object, the size of which is denoted by the three bit
operation qualifier.
6. An integrated circuit comprising:

a plurality of functional modules interconnected via a packet router, each functional module having packet handling circuitry for generating and receiving packets conveyed by the packet router;

wherein at least a first set of said functional modules acting as initiator
5 modules, have packet handling circuitry which includes request packet generation circuitry for generating request packets for implementing transactions, each request packet including a destination indicator identifying a destination of the packet and an operation field denoting the function to be implemented by the request packet, wherein the operation field comprises
10 eight bits of which a packet type denotes the type of the packet, four operation family bits denote the function to be implemented by the packet and three operation qualifier bits act to qualify the function, and

wherein a second set of said functional modules, acting as target modules, each having packet handling circuitry which includes packet receiver
15 logic for receiving said request packets and for generating respective response packets, wherein the packet type bit distinguishes request packets and response packets.

7. An integrated circuit comprising:

a plurality of functional modules interconnected via a packet router,
20 each functional module having packet handling circuitry for generating and receiving packets conveyed by the packet router;

wherein each functional module has packet handling circuitry which includes request packet generation circuitry for generating request packets for implementing transactions, and packet receiver logic for receiving request
25 packets and for generating respective response packets, each request packet including a destination indicator identifying a destination of the packet and an operation field denoting the function to be implemented by the

packet, wherein the operation field comprises eight bits of which a packet type distinguishes between request packets and response packets, four
30 operation family bits denote the function to be implemented by the packet and three operation qualifier bits act to qualify the function.

8. An integrated circuit according to claim 7, wherein each request packet includes a data object, the size of which is denoted by the three bit operation qualifier.

5 9. An initiator functional module for connection in an integrated circuit comprising:

an interface for supplying and receiving packets to and from the functional module, said interface being connected to a port for connecting the functional module to a packet router;

10 packet handling circuitry for handling said packets and including request packet generating logic which generates request packets for supply to the packet router via the interface, each request packet having a destination indicator identifying a destination of the packet and an operation field denoting the function to be implemented by the request packet, wherein the operation field comprises eight bits of which a packet type bit denotes the type
15 of the packet, four operation family bits denote the function to be implemented by the packet and three operation qualifier bits act to qualify the function.

10. A target functional module for connection in an integrated circuit comprising:

20 an interface for supplying and receiving packets to and from the functional module, said interface being connected to a port for connecting a functional module to a packet router;

25 packet receiver logic which is operable to receive request packets supplied from the packet router via the interface to the target functional module, each request packet having an operation field denoting the function to be implemented by the request packet, said operation field including four operation family bits denoting the function to be implemented by the packet, one of said operation family bits distinguishing between primitive memory access operations and complex memory access operations, wherein the packet receiver logic comprises means for detecting the status of said one operation
30 family bit to determine whether the memory access operation is primitive or compound.

11. A target function module as claimed in claim 10, which comprises means for generating respective response packets on receipt of each request packet, wherein the operation field of both request and response packets includes a single packet type bit which distinguishes between request packets
5 and response packets.

12. A method of implementing transactions in an integrated circuit comprising a plurality of functional modules interconnected via a packet router, the method comprising:

at one of said functional modules acting as an initiator module,
10 generating a request packet including a destination indicator identifying a destination of the packet and an operation field denoting the function to be implemented by the request packet, wherein the operation field comprises eight bits of which a packet type bit denotes the type of a packet, four operation family bits denote the function to be implemented by the packet and
15 three operation qualifier bits act to qualify the function;

at the destination indicated by the destination indicator, receiving said request packet and identifying the function to be implemented from the four operation family bits and the operation qualifier bits; and

generating a response packet for transmission to the initiator functional
20 module, wherein the packet type bit distinguishes between request packets and response packets.

13. A method according to claim 12, wherein the function in each request packet is a memory access operation.

14. A method according to claim 13, wherein one of said operation
25 family bits distinguishes between primitive memory access operations involving a single request packet and compound memory access operations involving a plurality of request packets, and wherein the method comprises detecting at the destination of the packet the status of this bit to determine whether a primitive memory access operation or a compound memory access
30 operation is to be implemented.

15. A method according to claim 12, wherein each request packet includes a data object, the size of which is denoted by the three bit operation qualifier, the method comprising at the destination of the packet, detecting the size of said data object from the three bit operation qualifier to determine how
5 to implement the function in the request packet.

16. A method according to claim 13, wherein said memory access operations include load, store, read-modify-write and swap operations.

17. An integrated circuit according to claim 3, wherein the memory access operation includes cache operations.

10 18. An integrated circuit according to claim 1, wherein the four operation family bits denote that the operation field is user defined.

19. A method according to claim 13, wherein said memory access operation includes cache operations.

15 20. A method according to claim 12, wherein said four operation family bits denote that the function defined in the operation field is user defined.
